

# **Model Archive Summary for Total Dissolved Solids at Station 07143672; Little Arkansas River at Highway 50 near Halstead, Kansas**

This model archive summary (MAS) summarizes the total dissolved solids (DS) model developed to compute hourly DS from January 1, 2007 onward. This model supersedes all models used from 1999 to 2007.

## **Site and Model Information**

Site number: 07143672

Site name: Little Arkansas River at Highway 50 near Halstead, Kansas

Location: Latitude 38°01'43", longitude 97°32'25" referenced to North American Datum of 1927, in NW 1/4 NE 1/4 NE 1/4 sec.28, T.23 S., R.2 W., Harvey County, Kansas, Hydrologic Unit 11030012.

Equipment: A YSI 6600 water-quality monitor equipped with sensors for water temperature, specific conductance (SC), dissolved oxygen, and pH, and a YSI Model 6136 turbidity sensor. The monitor is housed in a 4-inch plastic pipe. Readings from the YSI 6600 are recorded every 30 minutes and transmitted by way of satellite, hourly.

Date model was created: April 17, 2015

Model calibration data period: May 12, 1998 – August 28, 2014

Model application date: January 1, 2007 onward

## **Model Data**

All data were collected using U.S. Geological Survey (USGS) protocols and are stored in the National Water Information System (NWIS) database. The regression model is based on 150 concurrent measurements of total dissolved solids, streamflow, and specific conductance collected from May 12, 1998 through August 28, 2014. Samples were collected throughout the range of continuously observed hydrologic conditions. There were no samples below laboratory reporting levels. Summary statistics and the complete model-calibration dataset are provided below. Potential outliers were identified where the Studentized residual was greater than 3 or less than negative 3 and the Cook's D value exceeded the outlier test criteria. Samples collected March 13, 2001 and May 26, 2005 were deemed outliers and were removed from the dataset.

## **Sampling Details**

Cross-section samples are collected either from the downstream side of the bridge or instream, upstream of the bridge. Depending on stream depths and velocities, the equal-width-increment or multi-vertical method, or on occasion a single-point vertical, is used, and samples typically are composited for analysis. Cross-section samples are obtained during all discrete sample collections approximately every 2-3 months and during selected runoff events. A FISP US D-95 with a teflon bottle, cap, and nozzle depth integrating sampler is used from the bridge; and the DH-81 with a teflon bottle, cap, and nozzle hand sampler or a grab sample with a teflon bottle for wading samples. Samples are analyzed at the USGS National Water Quality Laboratory in Lakewood, Colorado; the Wichita Municipal Water and Wastewater Laboratory, Wichita, Kansas; the USGS Ohio Microbiology Lab in Columbus, Ohio; the USGS Organic Lab in Lawrence, Kansas; and ALS Environmental at various locations in the U.S.

## **Model Development**

Regression analysis was done using R by examining SC, streamflow, and other continuously measured data as explanatory variables for estimating total dissolved solids. A variety of models that predict DS and models that predict  $\log_{10}(\text{DS})$  were evaluated. The distribution of residuals was examined for normality, and plots of residuals (the difference between the measured and predicted values) as compared to predicted DS were examined for homoscedasticity (meaning that their departures from zero did not change substantially over the

range of predicted values). This comparison led to the conclusion that the most appropriate and reliable model would be one that estimated DS.

Specific conductance was selected as the best predictor of DS based on residual plots, relatively high adjusted coefficient of determination (adjusted  $R^2$ ) and relatively low model standard percentage error ( $MSPE$ ), prediction error sum of squares (PRESS), and Mallow's  $C_p$ . Values for all of the aforementioned statistics and metrics were computed for various models and are included below along with all relevant sample data and more in-depth statistical information.

## Model Summary

Summary of final regression analysis for total dissolved solids at site number 07143672.

Total dissolved solids-based model:

$$DS = 0.566 \times SC + 18.6$$

where

$DS$  = total dissolved solids in milligrams per liter (mg/L); and,

$SC$  = specific conductance in microsiemens per centimeter at 25 degrees Celsius ( $\mu\text{S}/\text{cm}$ ).

Specific conductance makes physical and statistical sense as an explanatory variable for dissolved solids. It makes physical sense because dissolved solids are partially comprised of ions and salts, which affect the conductivity of the water. This correlates well with SC because SC is a measure of the conductivity of water. Specific conductance makes statistical sense as an explanatory variable because it resulted in a model with low standard error, Mallow's  $C_p$  and PRESS values, and high  $R^2$  values. The model selected was the simplest model (one explanatory variable) even though some of the other models were marginally better statistically.

## Previous Models

<u>Model</u>	<u>Start year</u>	<u>End year</u>	<u>Model</u>
1.0	1999	2006	$DS = 0.551 \times SC + 25.3$
1.1	2007	--	$DS = 0.566 \times SC + 18.6$

## Total Dissolved Solids Record

The DS record is computed using this regression model and stored at the National Real-Time Water Quality (NRTWQ) Web site. Data are computed at hourly intervals. The complete water-quality record can be found at <http://nrtwq.usgs.gov/ks>.

## Remarks

None

## Definitions

DS: Total dissolved solids in mg/l (70300)

SC: Specific conductance in uS/cm @25C (00095)
